

# Lecture 4: IP Addresses, Sockets, and System Programming

COMP 332, Fall 2018

Victoria Manfredi

WESLEYAN  
UNIVERSITY

**Acknowledgements:** materials adapted from Computer Networking: A Top Down Approach 7<sup>th</sup> edition: ©1996-2016, J.F Kurose and K.W. Ross, All Rights Reserved as well as from slides by Abraham Matta at Boston University and some material from Computer Networks by Tannenbaum and Wetherall.

# Today

## 1. Announcements

- homework 1 due today, homework 2 posted
  - tictactoe.py solution code will be posted once homework1 submitted

## 2. Network applications

## 3. Network programming

- TCP sockets

## 4. Network tools

- Wireshark: looking at real traffic

# Internet Organization

## **IP ADDRESSES**

# Every device on Internet has an IP address

## IPv4 addresses

### – 4 bytes

- space of addresses: 0-255 . 0-255 . 0-255 . 0-255
- hostnames are human-readable, IP addresses are machine-readable

### – Loopback address: send traffic to yourself

- traffic sent here is “looped back” through network stack on machine on which sending process is running
- 127 . \* . \* . \*
- typically 127.0.0.1, also called localhost

### – Private subnet addresses

- 10 . \* . \* . \*
- 172.16-31 . \* . \*
- 192.168 . \* . \*

} Subnet: shared prefix  
portion of addr

## IPv6 addresses

### – 16 bytes: we’re running out of 4 byte addresses ...

# Who owns what address ranges?

## Amazon

- 50.19.\*.\* → 256 x 256 = 65536 addresses
- 54.239.98.\* → 256 addresses
- ...

## Facebook

- 57.240.0.0/17
- 157.240.10.0/24
- 157.240.1.0/24
- ...

## Google

- 64.233.160.0 to 64.233.191.255
- 66.102.0.0 to 66.102.15.255
- ...

## Wesleyan

- 129.133.21.\*
- ...

# How are IP addresses assigned?

## Your ISP or institution has block of IP addresses

- you are assigned one of those IP addresses
- (possible you will get NAT'd address ...)

## Static IP address

- **manual configuration**: set in network settings

## Dynamic IP address

- using **Dynamic Host Configuration Protocol (DHCP)** in network-layer
- client (you) broadcasts request for IP address
- DHCP server on network assigns you address from address pool
  - typically get IP address for fixed period of time
  - router can be configured to act as DHCP server

# Actually ...

Many hosts have multiple IP addresses

How?

- IP address associated with network interface not host
- network interface card (NIC): connects computer to network

A host may have 1 or more network interfaces

- my laptop has (at least) 2 NICs: 1 wireless and 1 wired (via USB)
- router needs at least two interfaces
  - otherwise can't connect multiple networks together
- Cisco core router: can have up to 10,000 interfaces!
  - one interface per link: router has many IP addresses

VirtualBox Virtual Machine (VM)

- you can set the number and type of network interfaces for VM

# What's my IP address?

## ifconfig

- what network interfaces does my machine have?
- what are my IP and MAC # addresses?
- configure/enable/disable an interface

Linux

Ethernet 0

IPv4 address

IPv6 address

Loopback  
address

```
vmanfred@curveball-VirtualBox:~$ ifconfig
eth0      Link encap:Ethernet  HWaddr 08:00:27:e2:65:b0

# What's host's IP address?

## Host

```
> host www.google.com
www.google.com has address 74.125.141.99
www.google.com has address 74.125.141.103
www.google.com has address 74.125.141.105
www.google.com has address 74.125.141.147
www.google.com has address 74.125.141.104
www.google.com has address 74.125.141.106
www.google.com has IPv6 address 2607:f8b0:400c:c06::93
```

## What's host name for IP address?

```
> host 8.8.8.8
8.8.8.8.in-addr.arpa domain name pointer google-public-dns-a.google.com.
```

# What's host's IP address?

dig

```
> dig www.google.com

```

# Is one IP address per machine enough?

## What happens if you run multiple network applications?

- many **processes** running on computer
  - process is program in execution

## How do messages received by computer get to right process?

- messages are addressed to (**IP address, port #**) pair
- different processes on computer will connect to network using same IP address but different **port numbers**

# 2 key functions of Internet core

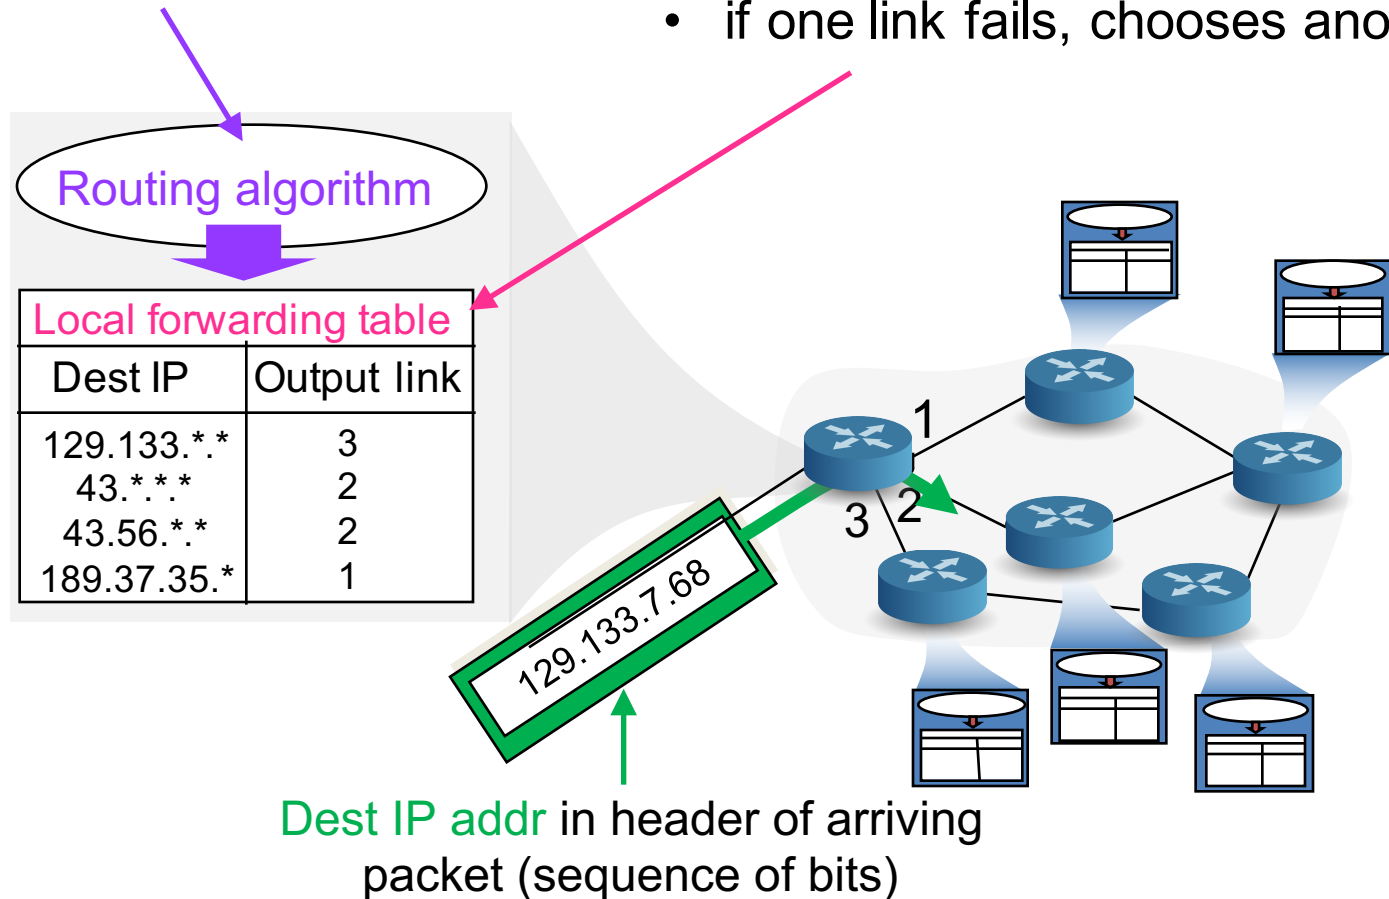

How does Internet router determine outgoing link for packet?

## 1. Routing

- view Internet as giant **graph**
- run **shortest path algorithms**

## 2. Forwarding

- use paths to choose best **output link** for packet **destination IP address**
- if one link fails, chooses another

# Routing of packets across Internet

Each router uses its forwarding table to choose outbound link based on packet's destination

# Network Applications

## **OVERVIEW**

# Creating a network app

## Write programs that

- run on (different) **end systems**
- **communicate** over network
- e.g., web server software communicates with browser software

## Q: Do we need to write software for **network-core devices**?

- **No**, network-core devices do not run user applications
- applications on end systems allows for rapid app development, propagation

# Client-server architecture

Client host requests and receives service  
from always on server host

## Server

- always-on, dedicated host
  - e.g., web server
- permanent IP address
- data centers for scaling

## Clients

- communicate with server
- may be intermittently connected
- may have dynamic IP addresses
- do not communicate directly with other clients

Client and server devices  
are not equivalent

# Peer-to-peer (P2P) architecture

Peers request service from other peers, provide service in return to other peers

## End systems directly communicate

- self scalability – new peers bring new service capacity, as well as new service demands
- minimal/no use of always-on server
- E.g., Skype, BitTorrent

## Complex management

- peers are intermittently connected and change IP addresses
- Q: why is this complex?

All devices are equivalent: a client can also be a server

# Processes communicating

## Process

- program in execution, running within a host

## Processes within same host

- communicate by using **inter-process communication** (defined by OS)

## Processes on different hosts

- communicate by **exchanging messages**

## Clients, servers

- **client process**
  - process that initiates communication
- **server process**
  - process that waits to be contacted

## Aside

- applications with **P2P architectures** also have client & server processes

Our goal learn how to build client/server applications that use sockets to communicate

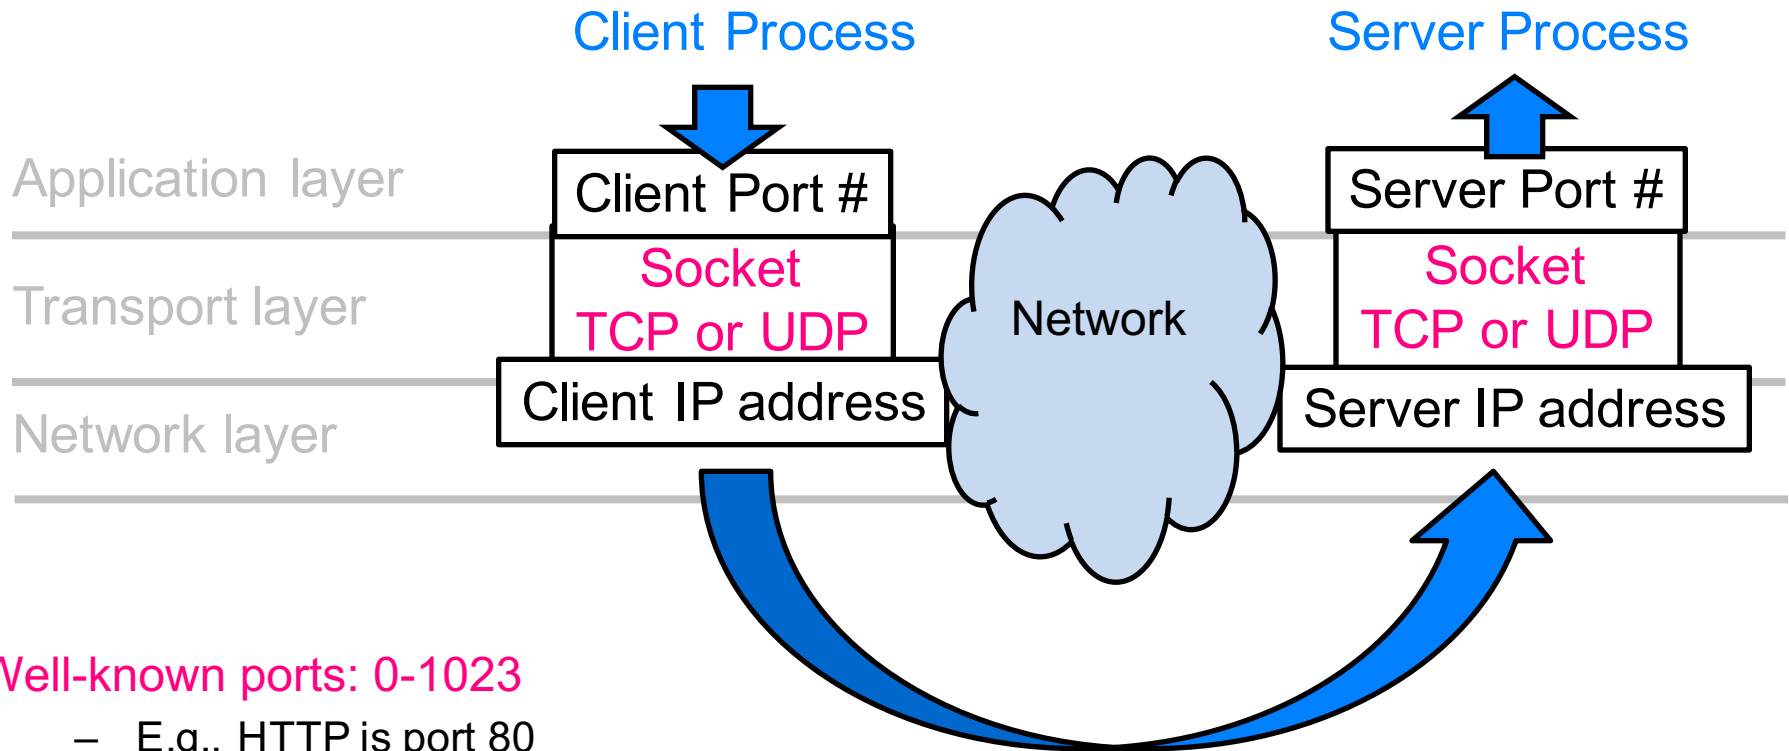

# Network Programming

## **OVERVIEW**

# How do two processes talk over a network?

## Via sockets

- interface transport layer provides to apps to access network
- connection endpoint with associated IP addr, port #

Well-known ports: 0-1023

- E.g., HTTP is port 80

Registered ports: 1023-49151

Available ports: 49152-65535

# Python socket module

## import socket

- gives access to BSD (Berkeley Socket Distribution) socket interface
  - POSIX sockets <-> Berkeley sockets <-> BSD sockets
  - available on pretty much every modern operating system

## Resources

- <https://docs.python.org/3/howto/sockets.html>
- <https://docs.python.org/3/library/socket.html>

## Socket exceptions

- <https://docs.python.org/3/library/socket.html#exceptions>

## You must read/write bytes from/to a socket

- encode string to bytes: `string.encode('utf-8')`
- decode string from bytes: `string.decode('utf-8')`

# Sockets

## Address families

- AF\_UNIX
  - local, inter-process communication
- AF\_INET4
  - Internet protocol v4
- AF\_INET6
  - Internet v6

Part of process identifier:  
e.g., <ip address, port>

To send HTTP message to  
wesleyan.edu web server

- IP address: 129.133.7.68
- port number: 80

## Socket types

- SOCK\_DGRAM
  - UDP packets
- SOCK\_STREAM
  - TCP packets
- SOCK\_RAW
  - don't let OS process transport header on packet, have OS send/receive raw packet

Different types of service  
offered by different  
socket types

# 2 main socket types for 2 transport services

## TCP (Transmission Control Protocol)

- **connection-oriented**
  - before data exchange takes place, a logical connection is first established
- **reliable, byte stream-oriented**
  - delivery is in-order, error- and loss-free, no duplication

App reads in-order, error-free bytes from socket

## UDP (User Datagram Protocol)

- **connection-less**
  - data is sent directly in a best-effort way
- **unreliable**
  - data can arrive out-of-order, be lost, corrupted, duplicated

App reads whatever is currently at socket, whether out-of-order, missing etc.

Any reliability must be implemented by app

# Send data (from python reference)

## `socket.send(bytes)` - TCP

- Send data to the socket. The socket **must be connected to a remote socket**. Returns the number of bytes sent. Applications are responsible for checking that all data has been sent; if only some of the data was transmitted, the application needs to attempt delivery of the remaining data

## `socket.sendall(bytes)` - TCP

- Send data to the socket. The socket **must be connected to a remote socket**. Unlike `send()`, this method continues to send data from bytes until either all data has been sent or an error occurs. None is returned on success. On error, an exception is raised, and there is no way to determine how much data, if any, was successfully sent.

## `socket.sendto(bytes, address)` - UDP

- Send data to the socket. The socket **should not be connected to a remote socket**, since the destination socket is specified by address.

# Receive data (from python reference)

## Socket.recv(num\_bytes)

- Receive data from the socket. The return value is a bytes object representing the data received. The maximum amount of data to be received at once is specified by *bufsize*.

# Partial Send/Recv

## socket.sendall()

- generally preferable to use to eliminate **partial send**

## socket.recv()

- app needs way to know whether it has read everything from socket
  - “end” flag
  - a priori knowledge of number of bytes to read
  - ...
- typically put recv() in while loop
  - keep reading until nothing left to read from socket

# Endianness

## Big endian

- big end first: largest byte (containing most significant bit) first

## Little endian

- little end first: smallest byte (containing least significant bit) first

## Network byte order

- big endian

## UTF-8 byte order

- stays the same regardless of endian-ness of machine
- i.e., you shouldn't need to worry about byte order

# Network Programming

## **TCP SOCKETS**

# Socket programming with TCP

## Client must first contact server before sending data

- server process must be running
  - creates socket (door) that welcomes client's contact

## How?

- create TCP socket
  - specify server IP addr, port #
- “handshake” occurs
  - TCP Syn/Synack/Ack exchanged
  - if succeeds, connection established, can send data

## When contacted by client

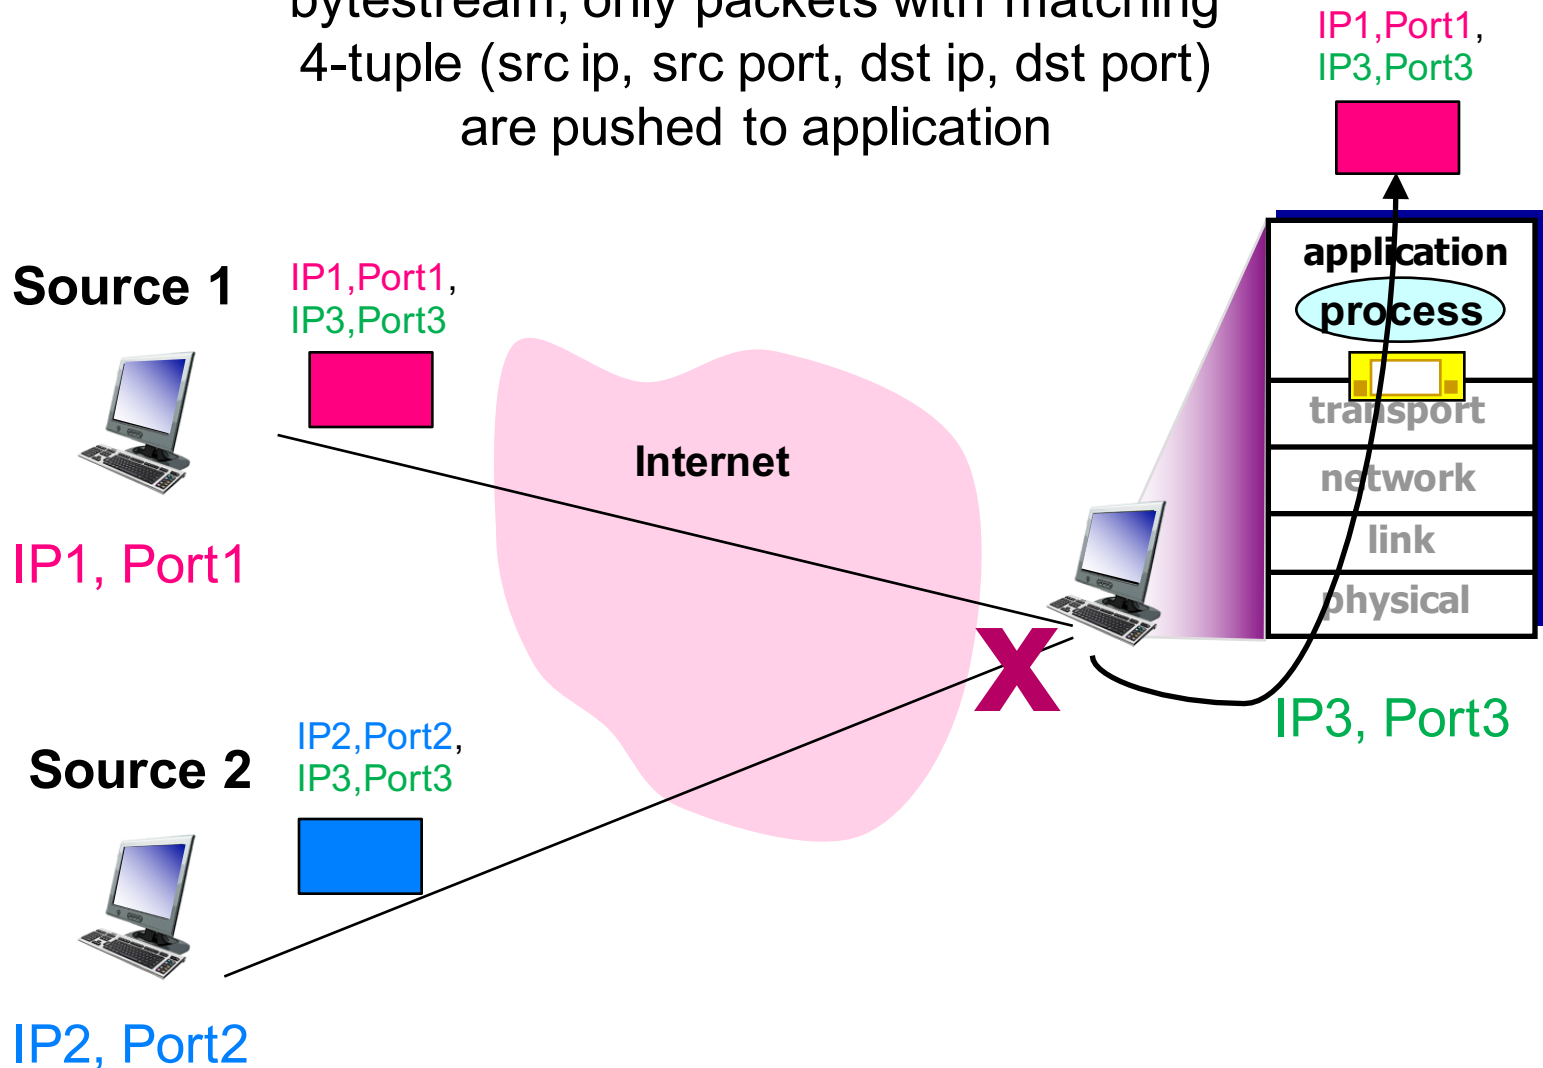

- server TCP creates new socket for server process to communicate with that particular client
  - allows server to talk with multiple clients
  - source port numbers used to distinguish clients

### Application viewpoint

TCP provides reliable, in-order byte-stream transfer (“pipe”) between client and server

# TCP Socket

Establish connection, read/write  
bytestream, only packets with matching  
4-tuple (src ip, src port, dst ip, dst port)  
are pushed to application

# Client/server socket interaction: TCP

Server running on serverIP

Create socket, port= x:

```
serverSocket =  
socket(AF_INET,SOCK_STREAM)
```

Wait for incoming  
connection request  
connectionSocket =  
serverSocket.accept()

read request from  
connectionSocket

write reply to  
connectionSocket

close  
connectionSocket

Client running on clientIP

create socket,  
connect to serverIP, port=x  
clientSocket = socket()

Send request using  
clientSocket

Read reply from  
clientSocket

Close clientSocket

TCP  
connection setup

# Application example

## 1. Client

- reads a line of characters (data) from its keyboard and sends data to server via socket

## 2. Server

- receives data from socket and converts characters to uppercase

## 3. Server

- sends modified data to client

## 4. Client

- receives modified data and displays line on its screen

# Application example: TCP server

## Python TCPServer

```
from socket import *
serverPort = 12000
serverSocket = socket(AF_INET,SOCK_STREAM)
serverSocket.bind(('',serverPort))
serverSocket.listen(1)
print 'The server is ready to receive'
```

create TCP welcoming  
socket →

server begins listening for  
incoming TCP requests →

loop forever →

server waits on accept()  
for incoming requests, new  
socket created on return

read bytes from socket (but  
not address as in UDP)

close connection to this  
client (but *not* welcoming  
socket)

```
while True:
    connectionSocket, addr = serverSocket.accept()
    sentence = connectionSocket.recv(1024).decode()
    capitalizedSentence = sentence.upper()
    connectionSocket.send(capitalizedSentence.
                           encode())
    connectionSocket.close()
```

# Application example: TCP client

## Python TCPClient

```
from socket import *
serverName = 'servername'
serverPort = 12000
clientSocket = socket(AF_INET, SOCK_STREAM)
clientSocket.connect((serverName,serverPort))
sentence = raw_input('Input lowercase sentence:')
clientSocket.send(sentence.encode())
modifiedSentence = clientSocket.recv(1024)
print ('From Server:', modifiedSentence.decode())
clientSocket.close()
```

create TCP socket for  
server, remote port  
12000

clientSocket.connect((serverName,serverPort))

No need to attach  
server name, port

modifiedSentence = clientSocket.recv(1024)

print ('From Server:', modifiedSentence.decode())

clientSocket.close()

# echo\_client.py and echo\_server.py

Look at code and run:  
available on class schedule

Packet sniffing

**WIRESHARK**

# How can I look at network traffic?

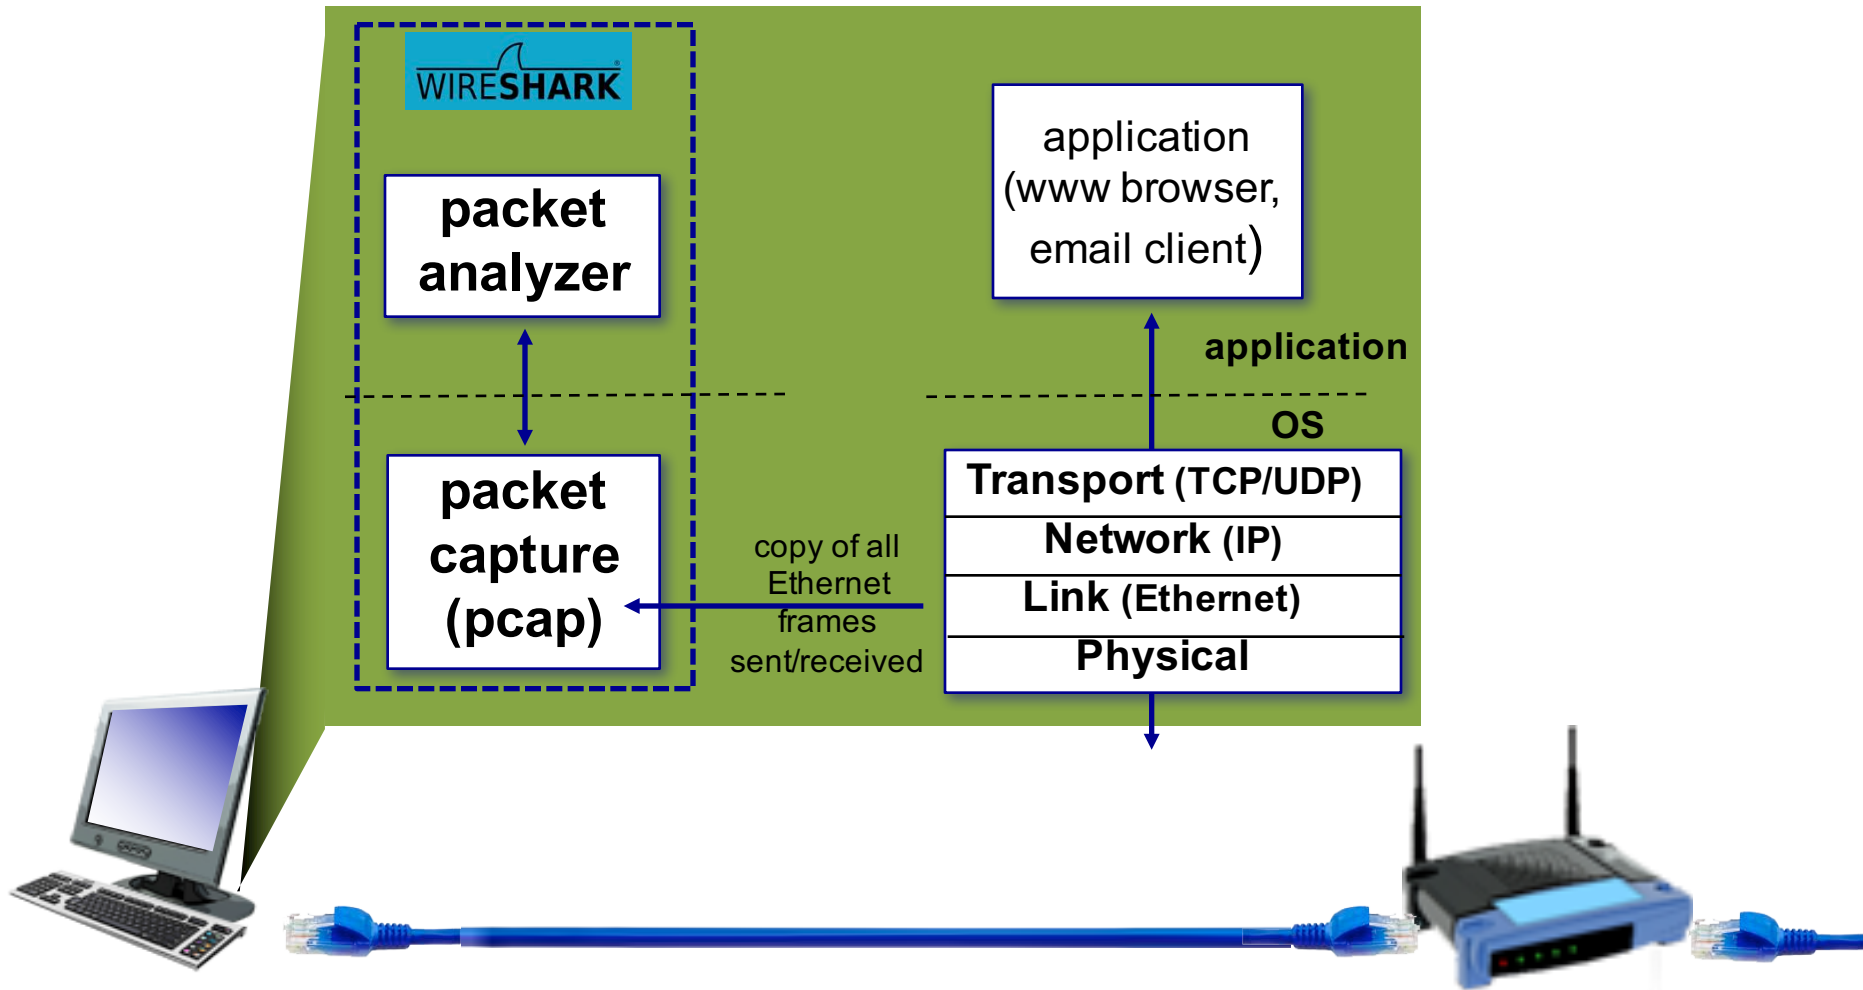

## Packet sniffer

- passively observes messages transmitted and received on a particular network interface by processes running on your computer
- often requires root privileges to run

## Popular packet sniffers

- Wireshark (also command-line version, tshark)
- tcpdump (Unix) and WinDump (Windows)
- use command line sniffers to analyze packet traces with bash script

# Packet sniffer operation

# Wireshark

## Install

- <https://www.wireshark.org/download.html>

## Run

- type Wireshark in terminal, or double-click icon
- Wireshark display may look different for Linux vs. Mac vs. Windows

Welcome to Wireshark

### Capture

# Add a filter

Only TCP traffic

See only TCP

TLS protocol runs over TCP

The image shows a Wireshark network traffic capture window. The top toolbar includes a search icon and a filter icon. A filter bar at the top contains the text 'tcp'. Below the filter bar is a table of captured packets. The table has columns for 'No.', 'Time', 'Source', 'Destination', 'Protocol', and 'Length'. The selected packet (No. 18) is highlighted in blue. Below the table, the packet details pane shows the structure of the selected packet: Ethernet II, Internet Protocol Version 4, and Transmission Control Protocol. The TCP details pane shows the sequence number, acknowledgment number, and flags. The packet bytes pane shows the raw data in hexadecimal and ASCII.

No.	Time	Source	Destination	Protocol	Length
18	0.356017	129.133.182.236	129.133.73.18	TCP	181
20	0.362499	129.133.182.236	129.133.73.18	TCP	66
21	0.393788	129.133.182.236	52.209.21.15	TCP	1434
22	0.393789	129.133.182.236	52.209.21.15	TLSv1.2	
25	0.499503	129.133.182.236	52.209.21.15	TCP	
30	1.725135	129.133.182.236	129.133.72.223	TCP	

Frame 18: 181 bytes on wire (1448 bits), 181 bytes captured (1448 bits) on interface 0  
Ethernet II, Src: Apple\_c5:b4:9a (78:31:c1:c5:b4:9a), Dst: JuniperN\_1e:18:01 (3c:8a:b0:1e:18:01)  
Internet Protocol Version 4, Src: 129.133.182.236, Dst: 129.133.73.18  
Transmission Control Protocol, Src Port: 62919 (62919), Dst Port: 8009 (8009), Seq: 1, Ack: 1, Len: 115  
Source Port: 62919  
Destination Port: 8009  
[Stream index: 1]  
[TCP Segment Len: 115]
